ABSTRACT

Urban freight transport recently faces many challenging problems, including high levels of traffic congestion, negative environmental impacts, and high energy consumption. Evaluation measures that can be done is by determining the routing and scheduling. PT. TMU was that produces various types of paints which are marketed to companies located in the industrial area of Kabupaten Bekasi and Jakarta. Determination of route by the company on the basis of the views and considerations the vehicle payload capacity and usability of the vehicle. This study was conducted to determine if the determination that can be done by considering the carrying capacity and time windows, as well as considering environmental aspects, reducing the impact of congestion, social aspects, and energy consumption. The model used in the form of concept Capacity Vehicle Routing Problem with Time Windows (CVRPTW) approach Savings on application Logware 5.0. This method are used in the case of the VRP by considering the capacity, and the minimum cost. The result of the calculation affects some aspects include savings generated mileage of 32.48%, efficiency payload capacity ratio of 84.8%, saving transportation costs 27.10, saving toll revenue 54.24%, emission reduction 3.95%, and then decrease in the number of citizen complaints as much as 2.22%.

Keywords: CVRPTW, Savings Heuristics Algorithm, City Logistics, Single Depot

1. INTRODUCTION

Socio-economically, the city is an environment with economic and the diverse business and is dominated by non-farm business activities include services, trade, transportation and industrial (Daluarti, 2009). The rapid development of urban areas in Indonesia could not be separated from the role of logistics. One of the key activities in logistics is on transport, in this case is freight transport.

Problem determination of routing and scheduling are the operational issues in transportation. Studies conducted in PT. TMU are transport operations in logistics. The Company are marketed to companies located in the industrial area of Kabupaten Bekasi and an expedition partner company to be sent to the outer islands of Java are located in parts of Jakarta.

The phenomena that occur in the company related to the transport logistics are expenses incurred from transportation activities undertaken by the company deemed high enough so that it takes the reduction of transport costs in order to save costs incurred by the company. In addition, the lack of good planning related to transportation logistics activities is a phenomenon of the next issue, so the determination of route and cost analysis of transportation before the operation deemed necessary by the company so that the company can carry out the necessary assessment of costs in transport logistics activities to be performed.

So in this case is necessary to make decisions about who can optimize the mileage or travel costs, travel time, number of operated vehicles and other resources are available by considering environmental aspects, reducing the impact of traffic congestion, social aspects, as well as energy consumption required from the movement of freight transport.

2. LITERATURE REVIEW

According to Ballou (2004), a better representation of the field may be reflected...
in the definition promulgated by the Council of Logistics Managements (CLM), a professional organization of logistics managers, educators, and practitioners formed in 1962 for the purposes of continuing education and fostering the interchange of ideas. Its definition: “Logistics is that part of the supply chain process that plans, implements, and controls the efficient, effective flow and storage of goods, services, and related information from the point of origin to the point of consumption in order to meet customers requirements.

Transportation is a key decision area within the logistics mix. Except for the cost of purchased goods, transportation absorbs, on the average, a higher percentage will represent one-half to two-third of total logistics cost (Ballou, 2004). Transportation is essential because no modern firm can operate without providing for the movement of its raw materials or its finished products.

Transportation decisions can involve mode selection, carrier routing, and vehicle scheduling (Ballou, 2004). Furthermore, urban freight transport plays a vital role in the sustainable development of cities (Taniguchi et al. 2001). A new area of transport planning has emerged called City Logistics. According to Taniguchi et al. (2001), City Logistics is the process of totally optimising urban logistics activities by considering the social, environmental, economic, financial and energy impacts of urban freight movement.

### 3. METHODOLOGY

Referring to the journal published by Taniguchi and Tamagawa (2005) entitled “Evaluating City Logistics Measures Considering The Behavior of Several Stakeholders”, There are five categories stakeholders which is in issue in this study include:

1. Freight carrier with criteria transportation cost.
2. Shippers with criteria transport travel time.
3. Urban expressway operators with criteria toll revenue.

---

**Route and Transportation Costs Analysis**

(Yogi Yogaswara)
4. Residents with criteria total NO\textsubscript{x} emissions in the network. The residents would make a complaint against the administrators whenever the NO\textsubscript{x} emissions for their zones exceed 50g per 1km.

5. Administrator with criteria total NO\textsubscript{x} emissions in the network and Total number of complaints from the residents.

\[
f_e = 6,372 - 0,716r_g - 0,193t_s - 1,392g_a - 1,412a + 0,138V - 0,001V^2 \quad (1)
\]

where:
\begin{itemize}
\item $f_e$: fuel economy (km/litre)
\item $r_g$: 1 for gravel road, 0 for asphalt pavement
\item $t_s$: stopped time (min.)
\item $g_a$: average gradient (%)
\item $a$: 1 when AC is on, 0 when AC is off
\item $V$: average travel speed (km/jam)
\end{itemize}

There are numerous undesirable negative effects from urban goods movement that can be present a direct risk to human health. Greenhouse gases produced from exhaust gases of trucks are a major concern in many cities. In this case, the emission factors used in determining the total NO\textsubscript{x} emissions of pollutants is to use a reference emission factor of the Indonesian Ministry of Environment drawn from scientific journals Srikandi Novianti dan Driejana (2009) entitled “The Influence of Factor Emission Characteristics In Transport-Induced Nitrogen Oxides (NO\textsubscript{x}) Emission Load Estimation” as can be seen in Table 4:

Then for the decision model of stakeholders level satisfaction city logistics system starts from stage calculation Capacity Vehicle Routing Problem With Time Windows (CVRPTW) approach Clarke & Wright Savings Heuristics Algorithm. This method is used for the VRP case by considering the capacity, and the minimum cost route followed by obstacles in the distribution system. In general, the savings equation is:

\[
S_{ij} = D_A - D_B = c_{ij} + c_{0j} - c_{ij} \quad (2)
\]

Source: Jens Lysgaard (1997)

Figure 1. Savings Concept Illustration

The steps in detail the methods savings as follows:
1. Set the distance at the beginning of each route for each node.
2. Calculate each pair using the savings equation (equation 2).
3. Create a list ranking of each pair are different.
4. Combine route when possible.
5. Next check back every couple route that have been generated.

General overview of the steps problem solving methodology can be seen in Figure 2 below in the form of a flowchart:

4. RESULTS

Figure 3a. Route Plot (a) Existing Condition (with 2 vehicles)

Figure 3b. Route Result are Built by Logware 5.0 (with 1 vehicle)

Figure 4. Comparison Chart of Total Transportation Cost

Figure 5. Comparison Chart of Transport Travel Time

Figure 6. Comparison Chart of Total Toll Revenue
5. CONCLUSION

Results calculated by Clarke and Wright Savings Algorithm approach using application Logware 5.0 obtained 3 route of distribution that can be done by the company include:

1. First route with the consumer point 0 – 1 – 2 – 0 by distance 66.9 km hauling total demand as much as 1961.06 kg,
2. Second route with the consumer point 0 – 3 – 5 – 9 – 12 – 10 – 0 by distance 114 km hauling total demand as much as 1544.47 kg, and
3. Third route with the consumer point 0 – 7 – 6 – 4 – 11 – 8 – 0 by distance 123,9 km hauling total demand as much as 1587,76 kg.

Where the whole targeted of node consumers using the vehicle in the form of a single ankle truck axis configuration with 1-1 (4 wheel). Furthermore, the data processing is done affects many aspects. These aspects include:

1. Savings generated mileage of 146.6 km (32.48%) so that an increase in the level of performance with the actual conditions of 1.48.
2. Efficiency payload capacity ratio (occupance rate) of 84.8% where there is a difference in the numbers with the existing conditions in the company amounted to 9.44% so that an increase in performance level of 1.17.
3. Savings transportation costs Rp. 221.746 (27.10%) so that an increase in performance level of 1.38 and savings toll revenue Rp. 48.000 (54.24%) with
the increase in performance level of 1.84.

4. Transport travel time during 610 minutes with the decrease in performance level of 0.80, where the difference of time with the actual conditions which produced for 119 minutes. Although there is a resulting decrease in the level of performance, but it does not happen constraints exceeds a predetermined of time windows.

5. Reduction of NOx emission 216.27 gram (3.85%) with the increase in performance level of 1.04.

6. Decrease in the number of complaints residents as much as 6 times (5.22%) with the increase in performance level of 1.06.
